Slides are adapted from:

Database System Concepts, 6th & 7th Ed. ©Silberschatz, Korth and Sudarshan

Outline

- Features of Good Relational Design
- Functional Dependency Theory
- Algorithms for Functional Dependencies
- Decomposition Using Multivalued Dependencies
- Atomic Domains and First Normal Form
- Decomposition Using Functional Dependencies
- More Normal Form
- Database-Design Process
- Modeling Temporal Data

What is Good Design?

→ Easier: What is Bad Design?

Combine Schemas?

- Suppose we combine *instructor* and *department* into *inst_dept*
 - (*No connection to relationship set inst_dept*)
- Result is possible repetition of information

<i>ID</i>	<i>name</i>	<i>salary</i>	<i>dept_name</i>	<i>building</i>	<i>budget</i>

Redundancy is Bad!

- Update Physics Department
 - Multiple tuples to update
 - Efficiency + potential for errors
- Delete Physics Department
 - Update multiple tuples
 - Efficiency + potential for errors
- Departments without instructor or instructors without departments
 - Need dummy department and dummy instructor
 - Makes aggregation harder and error-prone.

A Combined Schema Without Repetition

- Consider combining relations
 - $\text{sec_class}(\text{sec_id}, \text{building}, \text{room_number})$ and
 - $\text{section}(\text{course_id}, \text{sec_id}, \text{semester}, \text{year})$
- into one relation
 - $\text{section}(\text{course_id}, \text{sec_id}, \text{semester}, \text{year}, \text{building}, \text{room_number})$
- No repetition in this case

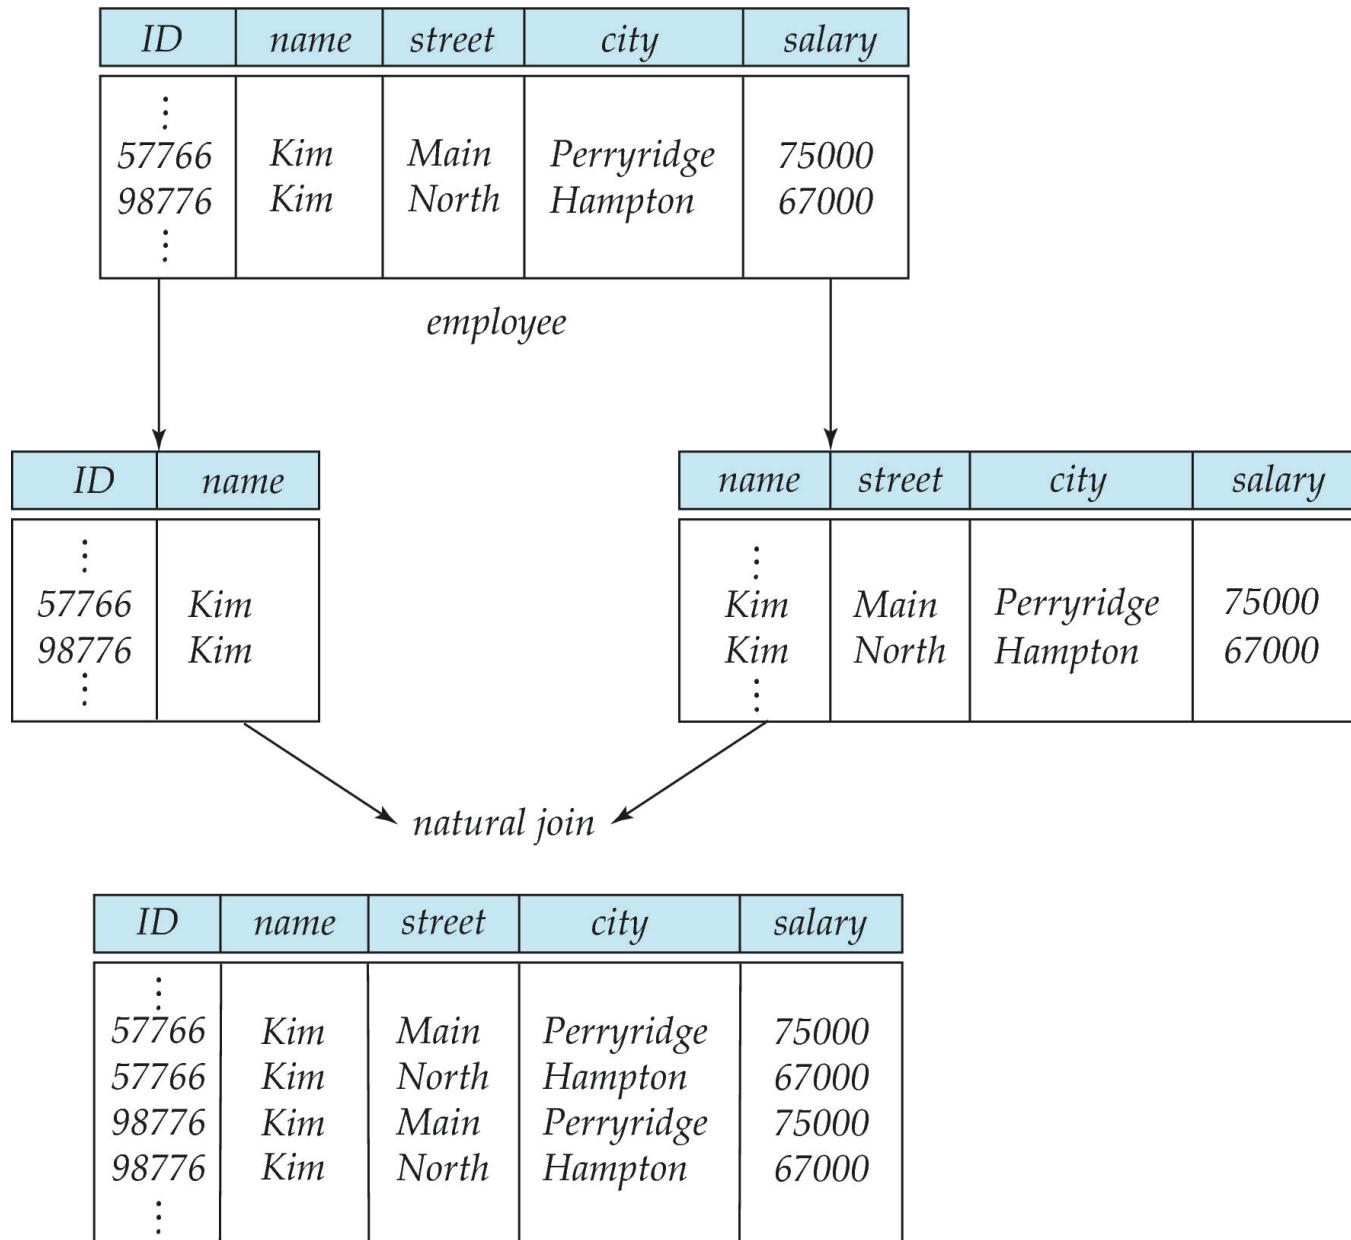

What About Smaller Schemas?

- Suppose we had started with *inst_dept*. How would we know to split up (**decompose**) it into *instructor* and *department*?
- Write a rule “if there were a schema (*dept_name*, *building*, *budget*), then *dept_name* would be a candidate key”
- Denote as a **functional dependency**:
$$\textit{dept_name} \rightarrow \textit{building}, \textit{budget}$$
- In *inst_dept*, because *dept_name* is not a candidate key, the building and budget of a department may have to be repeated.
 - This indicates the need to decompose *inst_dept*

What About Smaller Schemas?

- Not all decompositions are good. Suppose we decompose $\text{employee}(ID, name, street, city, salary)$ into
 $\text{employee1 } (ID, name)$
 $\text{employee2 } (name, street, city, salary)$
- The next slide shows how we lose information -- we cannot reconstruct the original employee relation -- and so, this is a **lossy decomposition**.

A Lossy Decomposition

Example of Lossless-Join Decomposition

- **Lossless join decomposition**
 - Splitting a table in a way that does not lose information
 - In other words, it is feasible to reconstruct the original table by joining the decomposed tables.
- Decomposition of $R = (A, B, C)$
$$R_1 = (A, B) \quad R_2 = (B, C)$$

A	B	C
α	1	A

α	1	A
β	2	B

r

$\Pi_{B,C}(r)$

$\Pi_A(r) \bowtie \Pi_B(r)$

A	B	C
α	1	A

α	1	A
β	2	B

Goal — Devise a Theory for the Following

- Decide whether a particular relation R is in “good” form.
- In the case that a relation R is not in “good” form, decompose it into a set of relations $\{R_1, R_2, \dots, R_n\}$ such that
 - each relation is in good form
 - the decomposition is a lossless-join decomposition
- Our theory is based on:
 - 1) Models of dependency between attribute values
 - **functional dependencies**
 - multivalued dependencies
 - 2) Concept of **lossless decomposition**
 - 3) **Normal Forms Based On**
 - Atomicity of values
 - Avoidance of redundancy
 - Lossless decomposition

Modeling Dependencies between Attribute Values:

Functional and Multivalued Dependencies

Functional Dependencies

- Constraints on the set of legal instances of the relation.
- Require that the value for a certain set of attributes determines uniquely the value for another set of attributes.
- A functional dependency
 - is a generalization of the notion of a *key*.
 - allows us to express constraints that uniquely identify the values of certain attributes.

Functional Dependencies (Cont.)

- Let R be a relation schema

$$\alpha \subseteq R \text{ and } \beta \subseteq R$$

- The **functional dependency**

$$\alpha \rightarrow \beta$$

holds on R if and only if for any legal relations $r(R)$, whenever any two tuples t_1 and t_2 of R agree on the attributes α , they also agree on the attributes β . That is,

$$t_1[\alpha] = t_2[\alpha] \Rightarrow t_1[\beta] = t_2[\beta]$$

- Example: Consider $R(A,B)$ with the following instance of R .

<table border="1"><tr><td>1</td><td>4</td></tr><tr><td>1</td><td>5</td></tr><tr><td>3</td><td>7</td></tr></table>	1	4	1	5	3	7	<p>A = 1 and B = 4 A = 1 and B = 5</p>
1	4						
1	5						
3	7						

- In this instance, $A \rightarrow B$ does **NOT** hold, but $B \rightarrow A$ does hold.

Functional Dependencies (Cont.)

- K is a superkey for relation schema R if and only if $K \rightarrow R$
- K is a candidate key for R if and only if
 - $K \rightarrow R$, and
 - for no $\alpha \subset K$, $\alpha \rightarrow R$
- Functional dependencies allow us to express constraints that cannot be expressed using superkeys. Consider the schema:
 $inst_dept (ID, name, salary, dept_name, building, budget)$.

We expect these functional dependencies to hold:

$$dept_name \rightarrow building$$

and $ID \rightarrow building$

but would not expect the following to hold:

$$dept_name \rightarrow salary$$

Use of Functional Dependencies

- We use functional dependencies to:
 - test relations to see if they are legal under a given set of functional dependencies.
 - If a relation r is legal under a set F of functional dependencies, we say that r **satisfies** F .
 - specify constraints on the set of legal relations
 - We say that F **holds on** R if all legal relations on R satisfy the set of functional dependencies F .
- Note: A specific instance of a relation schema may satisfy a functional dependency even if the functional dependency does not hold on all legal instances.
 - For example, a specific instance of *instructor* may, by chance, satisfy
$$name \rightarrow ID.$$

Functional Dependencies (Cont.)

- A functional dependency is **trivial** if it is satisfied by all relations
 - $A \rightarrow A$ is satisfied by all relations involving attribute A
 - Example:
 - $ID, name \rightarrow ID$
 - $name \rightarrow name$
 - In general, $\alpha \rightarrow \beta$ is trivial if $\beta \subseteq \alpha$

Functional-Dependency Theory

- We now consider the formal theory that tells us which functional dependencies are implied logically by a given set of functional dependencies.
- How do we get the initial set of FDs?
 - Semantics of the domain we are modeling
 - Has to be provided by a human (the designer)
- Example:
 - Relation Citizen(SSN, FirstName, LastName, Address)
 - We know that SSN is unique and a person has a unique SSN
 - Thus, $\text{SSN} \rightarrow \text{FirstName, LastName}$

Closure of a Set of Functional Dependencies

- Given a set F of functional dependencies, there are certain other functional dependencies that are logically implied by F .
 - For example: If $A \rightarrow B$ and $B \rightarrow C$, then we can infer that $A \rightarrow C$
- The set of **all** functional dependencies logically implied by F is the **closure** of F .
- We denote the *closure* of F by F^+ .
- F^+ is a superset of F .

Closure of a Set of Functional Dependencies

- We can find F^+ , the closure of F , by repeatedly applying **Armstrong's Axioms**:
 - if $\beta \subseteq \alpha$, then $\alpha \rightarrow \beta$ **(reflexivity)**
 - if $\alpha \rightarrow \beta$, then $\gamma \alpha \rightarrow \gamma \beta$ **(augmentation)**
 - if $\alpha \rightarrow \beta$, and $\beta \rightarrow \gamma$, then $\alpha \rightarrow \gamma$ **(transitivity)**
- These rules are
 - **sound** (generate only functional dependencies that actually hold), and
 - **complete** (generate all functional dependencies that hold).

Example

- $R = (A, B, C, G, H, I)$
 $F = \{ A \rightarrow B$
 $A \rightarrow C$
 $CG \rightarrow H$
 $CG \rightarrow I$
 $B \rightarrow H \}$
 - if $\beta \subseteq \alpha$, then $\alpha \rightarrow \beta$ **(reflexivity)**
 - if $\alpha \rightarrow \beta$, then $\gamma \alpha \rightarrow \gamma \beta$ **(augmentation)**
 - if $\alpha \rightarrow \beta$, and $\beta \rightarrow \gamma$, then $\alpha \rightarrow \gamma$ **(transitivity)**
- some members of F^+

Example

- $R = (A, B, C, G, H, I)$
 $F = \{ A \rightarrow B$
 $A \rightarrow C$
 $CG \rightarrow H$
 $CG \rightarrow I$
 $B \rightarrow H \}$
 - if $\beta \subseteq \alpha$, then $\alpha \rightarrow \beta$ **(reflexivity)**
 - if $\alpha \rightarrow \beta$, then $\gamma \alpha \rightarrow \gamma \beta$ **(augmentation)**
 - if $\alpha \rightarrow \beta$, and $\beta \rightarrow \gamma$, then $\alpha \rightarrow \gamma$ **(transitivity)**
- some members of F^+
 - $A \rightarrow H$
 - by transitivity from $A \rightarrow B$ and $B \rightarrow H$
 - $AG \rightarrow I$
 - by augmenting $A \rightarrow C$ with G , to get $AG \rightarrow CG$ and then transitivity with $CG \rightarrow I$
 - $CG \rightarrow HI$
 - by augmenting $CG \rightarrow I$ to infer $CG \rightarrow CGI$, and augmenting of $CG \rightarrow H$ to infer $CGI \rightarrow HI$, and then transitivity

Prove Additional Implications

- Prove or disprove the following rules from Armstrong's axioms
 - 1) $A \rightarrow B, C$ implies $A \rightarrow B$ and $A \rightarrow C$
 - 2) $A \rightarrow B$ and $A \rightarrow C$ implies $A \rightarrow B, C$
 - 3) $A, B \rightarrow B, C$ implies $A \rightarrow C$
 - 4) $A \rightarrow B$ and $C \rightarrow D$ implies $A, C \rightarrow B, D$

 - if $\beta \subseteq \alpha$, then $\alpha \rightarrow \beta$ **(reflexivity)**
 - if $\alpha \rightarrow \beta$, then $\gamma \alpha \rightarrow \gamma \beta$ **(augmentation)**
 - if $\alpha \rightarrow \beta$, and $\beta \rightarrow \gamma$, then $\alpha \rightarrow \gamma$ **(transitivity)**

Procedure for Computing F^+

- To compute the closure of a set of functional dependencies F :

$$F^+ = F$$

repeat

for each functional dependency f in F^+

 apply *reflexivity* and *augmentation* rules on f

 add the resulting functional dependencies to F^+

for each pair of functional dependencies f_1 and f_2 in F^+

if f_1 and f_2 can be combined using *transitivity*

then add the resulting functional dependency to F^+

until F^+ does not change any further

NOTE: We shall see an alternative procedure for this task later

Closure of Functional Dependencies (Cont.)

- Additional rules:
 - If $\alpha \rightarrow \beta$ holds and $\alpha \rightarrow \gamma$ holds, then $\alpha \rightarrow \beta\gamma$ holds (**union**)
 - If $\alpha \rightarrow \beta\gamma$ holds, then $\alpha \rightarrow \beta$ holds and $\alpha \rightarrow \gamma$ holds (**decomposition**)
 - If $\alpha \rightarrow \beta$ holds and $\beta \rightarrow \delta$ holds, then $\alpha\beta \rightarrow \delta$ holds (**pseudotransitivity**)

The above rules can be inferred from Armstrong's axioms.

Closure of Attribute Sets

- Given a set of attributes α , define the ***closure*** of α under F (denoted by α^+) as the set of attributes that are functionally determined by α under F
- Algorithm to compute α^+ , the closure of α under F

```
result :=  $\alpha$ ;  
while (changes to result) do  
    for each  $\beta \rightarrow \gamma$  in  $F$  do  
        begin  
            if  $\beta \subseteq \text{result}$  then result := result  $\cup$   $\gamma$   
        end
```

Example of Attribute Set Closure

- $R = (A, B, C, G, H, I)$
- $F = \{A \rightarrow B, A \rightarrow C, CG \rightarrow H, CG \rightarrow I, B \rightarrow H\}$
- $(AG)^+$
 1. $result = AG$
 2. $result = ABCG$ ($A \rightarrow C$ and $A \rightarrow B$)
 3. $result = ABCGH$ ($CG \rightarrow H$ and $CG \subseteq AGBC$)
 4. $result = ABCGHI$ ($CG \rightarrow I$ and $CG \subseteq AGBCH$)
- Is AG a candidate key?
 1. Is AG a super key?
 1. Does $AG \rightarrow R$? == Is $(AG)^+ \supseteq R$
 2. Is any subset of AG a superkey?
 1. Does $A \rightarrow R$? == Is $(A)^+ \supseteq R$
 2. Does $G \rightarrow R$? == Is $(G)^+ \supseteq R$

Uses of Attribute Closure

There are several uses of the attribute closure algorithm:

- Testing for *superkey*
 - To test if α is a superkey, we compute α^+ , and check if α^+ contains all attributes of R .
- Testing *functional dependencies*
 - To check if a functional dependency $\alpha \rightarrow \beta$ holds (or, in other words, is in F^+), just check if $\beta \subseteq \alpha^+$.
 - That is, we compute α^+ by using attribute closure, and then check if it contains β .
 - Is a simple and cheap test, and very useful
- Computing *closure of F*
 - For each $\gamma \subseteq R$, we find the closure γ^+ , and for each $S \subseteq \gamma^+$, we output a functional dependency $\gamma \rightarrow S$.

Canonical Cover

- We can reduce the effort spent in checking for violations by testing a simplified set of functional dependencies that has the same closure as the given set.
- Sets of functional dependencies may have redundant dependencies that can be inferred from the others
 - For example: $A \rightarrow C$ is redundant in: $\{A \rightarrow B, B \rightarrow C, A \rightarrow C\}$
 - Parts of a functional dependency may be redundant
 - E.g.: on RHS: $\{A \rightarrow B, B \rightarrow C, A \rightarrow CD\}$ can be simplified to
$$\{A \rightarrow B, B \rightarrow C, A \rightarrow D\}$$
 - E.g.: on LHS: $\{A \rightarrow B, B \rightarrow C, AC \rightarrow D\}$ can be simplified to
$$\{A \rightarrow B, B \rightarrow C, A \rightarrow D\}$$
- Intuitively, a canonical cover of F is a “minimal” set of functional dependencies equivalent to F , having no redundant dependencies or redundant parts of dependencies

Extraneous Attributes

- Consider a set F of functional dependencies and the functional dependency $\alpha \rightarrow \beta$ in F .
 - Attribute A is **extraneous** in α if $A \in \alpha$ and F logically implies $(F - \{\alpha \rightarrow \beta\}) \cup \{(\alpha - A) \rightarrow \beta\}$.
 - Attribute A is **extraneous** in β if $A \in \beta$ and the set of functional dependencies $(F - \{\alpha \rightarrow \beta\}) \cup \{\alpha \rightarrow (\beta - A)\}$ logically implies F .
- Note: implication in the opposite direction is trivial in each of the cases above, since a “stronger” functional dependency always implies a weaker one
- Example: Given $F = \{A \rightarrow C, AB \rightarrow C\}$
 - B is extraneous in $AB \rightarrow C$ because $\{A \rightarrow C, AB \rightarrow C\}$ logically implies $A \rightarrow C$ (i.e. the result of dropping B from $AB \rightarrow C$).
- Example: Given $F = \{A \rightarrow C, AB \rightarrow CD\}$
 - C is extraneous in $AB \rightarrow CD$ since $AB \rightarrow C$ can be inferred even after deleting C

Testing if an Attribute is Extraneous

- Consider a set F of functional dependencies and the functional dependency $\alpha \rightarrow \beta$ in F .
- To test if attribute $A \in \alpha$ is extraneous in α
 - compute $(\{\alpha\} - A)^+$ using the dependencies in F
 - check that $(\{\alpha\} - A)^+$ contains β ; if it does, A is extraneous in α
- To test if attribute $A \in \beta$ is extraneous in β
 - compute α^+ using only the dependencies in
$$F' = (F - \{\alpha \rightarrow \beta\}) \cup \{\alpha \rightarrow (\beta - A)\},$$
 - check that α^+ contains A ; if it does, A is extraneous in β

Canonical Cover

- A **canonical cover** for F is a set of dependencies F_c such that
 - F logically implies all dependencies in F_c , and
 - F_c logically implies all dependencies in F , and
 - No functional dependency in F_c contains an extraneous attribute, and
 - Each left side of functional dependency in F_c is unique.
- To compute a canonical cover for F :
repeat
 - Use the union rule to replace any dependencies in F
 $\alpha_1 \rightarrow \beta_1$ and $\alpha_1 \rightarrow \beta_2$ with $\alpha_1 \rightarrow \beta_1 \beta_2$
 - Find a functional dependency $\alpha \rightarrow \beta$ with an
 extraneous attribute either in α or in β
 /* Note: test for extraneous attributes done using F_c , not F^* */
 - If an extraneous attribute is found, delete it from $\alpha \rightarrow \beta$**until** F does not change
- Note: Union rule may become applicable after some extraneous attributes have been deleted, so it has to be re-applied

Computing a Canonical Cover

- $R = (A, B, C)$
 $F = \{A \rightarrow BC, B \rightarrow C, A \rightarrow B, AB \rightarrow C\}$
- Combine $A \rightarrow BC$ and $A \rightarrow B$ into $A \rightarrow BC$
 - Set is now $\{A \rightarrow BC, B \rightarrow C, AB \rightarrow C\}$
- A is extraneous in $AB \rightarrow C$
 - Check if the result of deleting A from $AB \rightarrow C$ is implied by the other dependencies
 - Yes: in fact, $B \rightarrow C$ is already present!
 - Set is now $\{A \rightarrow BC, B \rightarrow C\}$
- C is extraneous in $A \rightarrow BC$
 - Check if $A \rightarrow C$ is logically implied by $A \rightarrow B$ and the other dependencies
 - Yes: using transitivity on $A \rightarrow B$ and $B \rightarrow C$.
 - Can use attribute closure of A in more complex cases
- The canonical cover is: $A \rightarrow B \quad B \rightarrow C$

Lossless Join-Decomposition Dependency Preservation

Lossless-join Decomposition

- For the case of $R = (R_1, R_2)$, we require that for all possible relations r on schema R

$$r = \Pi_{R1}(r) \bowtie \Pi_{R2}(r)$$

- A decomposition of R into R_1 and R_2 is *lossless join* if at least one of the following dependencies is in F^+ :
 - $R_1 \cap R_2 \rightarrow R_1$ if $R_1 \cap R_2$ forms a superkey of either R_1 or R_2 !
 - $R_1 \cap R_2 \rightarrow R_2$
- The above functional dependencies are a sufficient condition for lossless join decomposition; the dependencies are a necessary condition only if all constraints are functional dependencies

Example

- $R = (A, B, C)$
 $F = \{A \rightarrow B, B \rightarrow C\}$
 - Can be decomposed in two different ways
- $R_1 = (A, B), R_2 = (B, C)$
 - Lossless-join decomposition:
$$R_1 \cap R_2 = \{B\} \text{ and } B \rightarrow BC$$
 - Dependency preserving
- $R_1 = (A, B), R_2 = (A, C)$
 - Lossless-join decomposition:
$$R_1 \cap R_2 = \{A\} \text{ and } A \rightarrow AB$$
 - Not dependency preserving
(cannot check $B \rightarrow C$ without computing $R_1 \bowtie R_2$)

Dependency Preservation

- Let F_i be the set of dependencies F^+ that include only attributes in R_i .
 - A decomposition is **dependency preserving**, if
$$(F_1 \cup F_2 \cup \dots \cup F_n)^+ = F^+$$
 - If it is not, then checking updates for violation of functional dependencies may require computing joins, which is expensive.

Testing for Dependency Preservation

- To check if a dependency $\alpha \rightarrow \beta$ is preserved in a decomposition of R into R_1, R_2, \dots, R_n we apply the following test (with attribute closure done with respect to F)
 - $result = \alpha$
while (changes to $result$) do
 for each R_i in the decomposition
 $t = (result \cap R_i)^+ \cap R_i$
 $result = result \cup t$
 - If $result$ contains all attributes in β , then the functional dependency $\alpha \rightarrow \beta$ is preserved.
- We apply the test on all dependencies in F to check if a decomposition is dependency preserving
- This procedure takes polynomial time, instead of the exponential time required to compute F^+ and $(F_1 \cup F_2 \cup \dots \cup F_n)^+$

Example

- $R = (A, B, C)$
 $F = \{A \rightarrow B$
 $\quad B \rightarrow C\}$
Key = {A}
- Decomposition $R_1 = (A, B), R_2 = (B, C)$
 - Lossless-join decomposition
 - Dependency preserving

Normal Forms

So Far

- **Theory of dependencies**
- **Decompositions and ways to check whether they are “good”**
 - Lossless
 - Dependency preserving
- **Next: What is missing?**
 - Define what constitutes a good relation
 - Normal forms
 - How to check for a good relation
 - Test normal forms
 - How to achieve a good relation
 - Translate into normal form
 - Involves decomposition

Goals of Normalization

- Let R be a relation scheme with a set F of functional dependencies.
- Decide whether a relation scheme R is in “good” form.
- In the case that a relation scheme R is not in “good” form, decompose it into a set of relation scheme $\{R_1, R_2, \dots, R_n\}$ such that
 - each relation scheme is in good form
 - the decomposition is a lossless-join decomposition
 - Preferably, the decomposition should be dependency preserving.

First Normal Form

- A relational schema R is in **first normal form** if the domains of all attributes of R are atomic
- A domain is **atomic** if its elements are considered to be indivisible units
 - Examples of non-atomic domains:
 - Set of names, composite attributes
 - Identification numbers like CS101 that can be broken up into parts
- Non-atomic values complicate storage and encourage redundant (repeated) storage of data
 - Example: Set of accounts stored with each customer, and set of owners stored with each account
 - We assume all relations are in first normal form.

First Normal Form (Cont'd)

- Atomicity is actually a property of how the elements of the domain are used.
 - Example: Strings would normally be considered indivisible
 - Suppose that students are given roll numbers which are strings of the form *CS0012* or *EE1127*
 - If the first two characters are extracted to find the department, the domain of roll numbers is not atomic.
 - Doing so is a bad idea: leads to encoding of information in application program rather than in the database.

Second Normal Form

- A relation schema R in **1NF** is in **second normal form (2NF)** iff
 - No non-prime attribute depends on parts of a candidate key.
 - An attribute is non-prime if it does not belong to any candidate key for R .

Second Normal Form Example

- $R(A,B,C,D)$
 - $A,B \rightarrow C,D$
 - $A \rightarrow C$
 - $B \rightarrow D$
- $\{A,B\}$ is the only candidate key
- R is not in 2NF, because $A \rightarrow C$ where A is part of a candidate key and C is not part of a candidate key.
- Interpretation $R(A,B,C,D)$ is **Advisor**(InstrSSN, StudentID, InstrName, StudentName)
 - Indication that we are putting stuff together that does not belong together

Second Normal Form Interpretation

- Why is a dependency on parts of a candidate key bad?
 - That is why is a relation that is not in 2NF bad?
- 1) A dependency on part of a candidate key indicates *potential for redundancy*
 - **Advisor**(InstrSSN, StudentID, InstrName, StudentName)
 - $\text{StudentID} \rightarrow \text{StudentName}$
 - If a student is advised by multiple instructors we record his name several times
- 2) A dependency on parts of a candidate key shows that some attributes are *unrelated* to other parts of a candidate key
 - That means the table should be split.

2NF is What We Want?

- **Instructor**(Name, Salary, DepName, DepBudget) = I(A,B,C,D)
 - A → B,C,D
 - C → D
- {Name} is the only candidate key
- I is in 2NF
- However, as we have seen before I still has update redundancy that can cause update anomalies
 - We repeat the budget of a department if there is more than one instructor working for that department

Third Normal Form

- A relation schema R is in **third normal form (3NF)** if for **all**:

$$\alpha \rightarrow \beta \text{ in } F^+$$

at least one of the following holds:

- $\alpha \rightarrow \beta$ is trivial (i.e., $\beta \in \alpha$)
- α is a superkey for R
- Each attribute A in $\beta - \alpha$ is contained in a candidate key for R .
(NOTE: each attribute may be in a different candidate key)

Alternatively,

- Every attribute depends directly on a candidate key, i.e., for every attribute A there is a dependency $X \rightarrow A$, but no dependency $Y \rightarrow A$ where Y is not a candidate key

3NF Example

- **Instructor**(Name, Salary, DepName, DepBudget) = I(A,B,C,D)
 - A → B,C,D
 - C → D
- {Name} is the only candidate key
- I is in 2NF
- I is not in 3NF

Testing for 3NF

- Optimization: Need to check only FDs in F , need not check all FDs in F^+ .
- Use attribute closure to check for each dependency $\alpha \rightarrow \beta$, if α is a superkey.
- If α is not a superkey, we have to verify if each attribute in β is contained in a candidate key of R
 - This test is rather more expensive since it involves finding candidate keys
 - Testing for 3NF has been shown to be *NP-hard*
 - Interestingly, decomposition into the third normal form (described shortly) can be done in polynomial time.

3NF Decomposition Algorithm

Let F_c be a canonical cover for F ;
 $i := 0$;

for each functional dependency $\alpha \rightarrow \beta$ in F_c **do**

if none of the schemas R_j , $1 \leq j \leq i$ contains $\alpha \beta$

then begin

$i := i + 1$;

$R_i := \alpha \beta$

end

if none of the schemas R_j , $1 \leq j \leq i$ contains a candidate key for R

then begin

$i := i + 1$;

$R_i :=$ any candidate key for R ;

end

/* Optionally, remove redundant relations */

repeat

if any schema R_j is contained in another schema R_k

then /* delete R_j */

$R_j = R_{j+1};$

$i=i-1;$

return (R_1, R_2, \dots, R_i)

3NF Decomposition Algorithm (Cont.)

- Above algorithm ensures:
 - Each relation schema R_i is in 3NF
 - Decomposition is dependency preserving and lossless-join
 - Proof of correctness is at the end of this presentation

3NF Decomposition: An Example

- Relation schema:

$\text{cust_banker_branch} = (\underline{\text{customer_id}}, \underline{\text{employee_id}}, \text{branch_name}, \text{type})$

- The functional dependencies for this relation schema are:

1. $\text{customer_id}, \text{employee_id} \rightarrow \text{branch_name}, \text{type}$
2. $\text{employee_id} \rightarrow \text{branch_name}$
3. $\text{customer_id}, \text{branch_name} \rightarrow \text{employee_id}$

- We first compute a canonical cover

- branch_name is extraneous in the r.h.s. of the 1st dependency
- No other attribute is extraneous, so we get $F_C =$

$\text{customer_id}, \text{employee_id} \rightarrow \text{type}$
 $\text{employee_id} \rightarrow \text{branch_name}$
 $\text{customer_id}, \text{branch_name} \rightarrow \text{employee_id}$

3NF Decomposition Example (Cont.)

- The **for** loop generates following 3NF schema:

$(\underline{customer_id}, \underline{employee_id}, type)$

$(\underline{employee_id}, branch_name)$

$(\underline{customer_id}, branch_name, \underline{employee_id})$

- Observe that $(\underline{customer_id}, \underline{employee_id}, type)$ contains a candidate key of the original schema, so no further relation schema needs be added

- At the end of the for loop, detect and delete schemas, such as $(\underline{employee_id}, branch_name)$, which are subsets of other schemas
 - result will not depend on the order in which FDs are considered
- The resultant simplified 3NF schema is:

$(\underline{customer_id}, \underline{employee_id}, type)$

$(\underline{customer_id}, branch_name, \underline{employee_id})$

Another 3NF Example

- Relation *dept_advisor*:
 - ***dept_advisor*** (*s_ID*, *i_ID*, *dept_name*)
 $F = \{s_ID, dept_name \rightarrow i_ID,$
 $i_ID \rightarrow dept_name\}$
 - Two candidate keys: *s_ID*, *dept_name*, and *i_ID*, *s_ID*
 - *R* is in 3NF
 - $s_ID, dept_name \rightarrow i_ID$
 - *s_ID, dept_name* is a superkey
 - $i_ID \rightarrow dept_name$
 - *dept_name* is contained in a candidate key

Redundancy in 3NF

- There is some redundancy in this schema $\text{dept_advisor}(s_ID, i_ID, \text{dept_name})$
- Example of problems due to redundancy in 3NF
 - $R = (J, K, L)$
 $F = \{JK \rightarrow L, L \rightarrow K\}$
- Repetition of information (e.g., the relationship I_1, k_1)
 - $(i_ID, \text{dept_name})$
- Need to use null values (e.g., to represent the relationship I_2, k_2 where there is no corresponding value for J).
 - $(i_ID, \text{dept_name})$ if there is no separate relation mapping instructors to departments

J	L	K
j_1	I_1	k_1
j_2	I_1	k_1
j_3	I_1	k_1
$null$	I_2	k_2

Boyce-Codd Normal Form

A relation schema R is in BCNF with respect to a set F of functional dependencies if for all functional dependencies in F^+ of the form

$$\alpha \rightarrow \beta$$

where $\alpha \subseteq R$ and $\beta \subseteq R$, at least one of the following holds:

- $\alpha \rightarrow \beta$ is trivial (i.e., $\beta \subseteq \alpha$)
- α is a superkey for R

Example schema *not* in BCNF:

instr_dept (ID, name, salary, dept_name, building, budget)

because $dept_name \rightarrow building, budget$ holds on *instr_dept*, but $dept_name$ is not a superkey

BCNF and Dependency Preservation

- If a relation is in BCNF, it is in 3NF.
- Constraints, including functional dependencies, are costly to check in practice unless they pertain to only one relation
- Because it is **not always** possible to achieve **both BCNF and dependency preservation**, we consider *third normal form* that allows us to preserve dependencies.

Testing for BCNF

- To check if a non-trivial dependency $\alpha \rightarrow \beta$ causes a violation of BCNF
 1. compute α^+ (the attribute closure of α), and
 2. verify that it includes all attributes of R , that is, it is a superkey of R .
- **Simplified test:** To check if a relation schema R is in BCNF, it suffices to check only the dependencies in the given set F for violation of BCNF, rather than checking all dependencies in F^+ .
 - If none of the dependencies in F causes a violation of BCNF, then none of the dependencies in F^+ will cause a violation of BCNF either.
- However, **simplified test using only F is incorrect when testing a relation in a decomposition of R**
 - Consider $R = (A, B, C, D, E)$, with $F = \{ A \rightarrow B, BC \rightarrow D \}$
 - Decompose R into $R_1 = (A, B)$ and $R_2 = (A, C, D, E)$
 - Neither of the dependencies in F contain only attributes from (A, C, D, E) so we might be misled into thinking R_2 satisfies BCNF.
 - In fact, dependency $AC \rightarrow D$ in F^+ shows R_2 is not in BCNF.

Testing Decomposition for BCNF

- To check if a relation R_i in a decomposition of R is in BCNF,
 - Either test R_i for BCNF with respect to the **restriction** of F to R_i (that is, all FDs in F^+ that contain only attributes from R_i)
 - or use the original set of dependencies F that hold on R , but with the following test:
 - for every set of attributes $\alpha \subseteq R_i$, check that α^+ (the attribute closure of α) either includes no attribute of $R_i - \alpha$, or includes all attributes of R_i .
 - If the condition is violated by some $\alpha \rightarrow \beta$ in F , the dependency
$$\alpha \rightarrow (\alpha^+ - \alpha) \cap R_i$$
can be shown to hold on R_i , and R_i violates BCNF.
 - We use above dependency to decompose R_i

Decomposing a Schema into BCNF

- Suppose we have a schema R and a non-trivial dependency $\alpha \rightarrow \beta$ causes a violation of BCNF.

We decompose R into:

- $(\alpha \cup \beta)$
- $(R - (\beta - \alpha))$

- In our example,

- $instr_dept (ID, name, salary, \underline{dept_name}, building, budget)$
- $dept_name \rightarrow building, budget$
- $\alpha = dept_name$
- $\beta = building, budget$

and $inst_dept$ is replaced by

- $(\alpha \cup \beta) = (dept_name, building, budget)$
- $(R - (\beta - \alpha)) = (ID, name, salary, dept_name)$

BCNF Decomposition Algorithm

```
result := {R };
done := false;
compute  $F^+$ ;
while (not done) do
  if (there is a schema  $R_i$  in result that is not in BCNF)
    then begin
      let  $\alpha \rightarrow \beta$  be a nontrivial functional dependency that
        holds on  $R_i$  such that  $\alpha \rightarrow R_i$  is not in  $F^+$ ,
        and  $\alpha \cap \beta = \emptyset$ ;
      result := (result -  $R_i$ )  $\cup$  ( $R_i - \beta$ )  $\cup$  ( $\alpha, \beta$ );
    end
  else done := true;
```

Note: each R_i is in BCNF, and decomposition is lossless-join.

Example of BCNF Decomposition

- $R = (A, B, C)$
 $F = \{A \rightarrow B$
 $\quad B \rightarrow C\}$
Key = {A}
- R is not in BCNF ($B \rightarrow C$ but B is not superkey)
- Decomposition
 - $R_1 = (B, C)$
 - $R_2 = (A, B)$

Example of BCNF Decomposition

- $\text{class}(\text{course_id}, \text{title}, \text{dept_name}, \text{credits}, \text{sec_id}, \text{semester}, \text{year}, \text{building}, \text{room_number}, \text{capacity}, \text{time_slot_id})$
- Functional dependencies:
 - $\text{course_id} \rightarrow \text{title}, \text{dept_name}, \text{credits}$
 - $\text{building}, \text{room_number} \rightarrow \text{capacity}$
 - $\text{course_id}, \text{sec_id}, \text{semester}, \text{year} \rightarrow \text{building}, \text{room_number}, \text{time_slot_id}$
- A candidate key $\{\text{course_id}, \text{sec_id}, \text{semester}, \text{year}\}$.
- BCNF Decomposition:
 - $\text{course_id} \rightarrow \text{title}, \text{dept_name}, \text{credits}$ holds
 - but course_id is not a superkey.
 - We replace class by:
 - $\text{course}(\text{course_id}, \text{title}, \text{dept_name}, \text{credits})$
 - $\text{class-1}(\text{course_id}, \text{sec_id}, \text{semester}, \text{year}, \text{building}, \text{room_number}, \text{capacity}, \text{time_slot_id})$

BCNF Decomposition (Cont.)

- *course* is in BCNF
 - How do we know this?
- *building, room_number*→*capacity* holds on *class-1*
 - but $\{building, room_number\}$ is not a superkey for *class-1*.
 - We replace *class-1* by:
 - *classroom* (*building, room_number, capacity*)
 - *section* (*course_id, sec_id, semester, year, building, room_number, time_slot_id*)
- *classroom* and *section* are in BCNF.

BCNF and Dependency Preservation

- $R = (J, K, L)$

$$F = \{JK \rightarrow L \\ L \rightarrow K\}$$

Two candidate keys = JK and JL

- R is not in BCNF
- Any decomposition of R will fail to preserve

$$JK \rightarrow L$$

This implies that testing for $JK \rightarrow L$ requires a join

How good is BCNF?

- There are database schemas in BCNF that do not seem to be sufficiently normalized
- Consider a relation

inst_info (ID, child_name, phone)

- where an instructor may have more than one phone and can have multiple children

<i>ID</i>	<i>child_name</i>	<i>phone</i>
99999	David	512-555-1234
99999	David	512-555-4321
99999	William	512-555-1234
99999	William	512-555-4321

inst_info

How good is BCNF? (Cont.)

- There are no non-trivial functional dependencies and therefore the relation is in BCNF
- Insertion anomalies – i.e., if we add a phone 981-992-3443 to 99999, we need to add two tuples
 - (99999, David, 981-992-3443)
 - (99999, William, 981-992-3443)

How good is BCNF? (Cont.)

- Therefore, it is better to decompose *inst_info* into:

inst_child

<i>ID</i>	<i>child_name</i>
99999	David
99999	David
99999	William
99999	Willian

inst_phone

<i>ID</i>	<i>phone</i>
99999	512-555-1234
99999	512-555-4321
99999	512-555-1234
99999	512-555-4321

This suggests the need for higher normal forms, such as Fourth Normal Form (4NF), which we shall see later.

Comparison of BCNF and 3NF

- It is always possible to decompose a relation into a set of relations that are in 3NF such that:
 - the decomposition is lossless
 - the dependencies are preserved
- It is always possible to decompose a relation into a set of relations that are in BCNF such that:
 - the decomposition is lossless
 - it may not be possible to preserve dependencies.

Summary Normal Forms

- BCNF → 3NF → 2NF → 1NF

- **1NF**
 - atomic attributes
- **2NF**
 - no non-trivial dependencies of non-prime attributes on parts of the key
- **3NF**
 - no transitive non-trivial dependencies on the key
- **BCNF**
 - only non-trivial dependencies on a superkey

Design Goals Revisited

- Goal for a relational database design is:
 - BCNF
 - Lossless join.
 - Dependency preservation.
- If we cannot achieve this, we accept one of
 - Lack of dependency preservation
 - Redundancy due to use of 3NF
- Interestingly, SQL does not provide a direct way of specifying functional dependencies other than superkeys.
 - Can specify FDs using assertions, but they are expensive to test

Multivalued Dependencies and 4NF, 5NF

Multivalued Dependencies

- Suppose we record names of children, and phone numbers for instructors:
 - $inst_child(ID, child_name)$
 - $inst_phone(ID, phone_number)$
- If we were to combine these schemas to get
 - $inst_info(ID, child_name, phone_number)$
 - Example data:
 - (99999, David, 512-555-1234)
 - (99999, David, 512-555-4321)
 - (99999, William, 512-555-1234)
 - (99999, William, 512-555-4321)
- This relation is in BCNF
 - Why?

Multivalued Dependencies (MVDs)

- Let R be a relation schema and let $\alpha \subseteq R$ and $\beta \subseteq R$. The **multivalued dependency**

$$\alpha \rightarrow\!\!\!\rightarrow \beta$$

holds on R if in any legal relation $r(R)$, for all pairs of tuples t_1 and t_2 in r such that $t_1[\alpha] = t_2[\alpha]$, there exist tuples t_3 and t_4 in r such that:

$$\begin{aligned}t_1[\alpha] &= t_2[\alpha] = t_3[\alpha] = t_4[\alpha] \\t_3[\beta] &= t_1[\beta] \\t_3[R - \beta] &= t_2[R - \beta] \\t_4[\beta] &= t_2[\beta] \\t_4[R - \beta] &= t_1[R - \beta]\end{aligned}$$

MVD (Cont.)

- Tabular representation of $\alpha \rightarrow\!\!\!\rightarrow \beta$

	α	β	$R - \alpha - \beta$
t_1	$a_1 \dots a_i$	$a_{i+1} \dots a_j$	$a_{j+1} \dots a_n$
t_2	$a_1 \dots a_i$	$b_{i+1} \dots b_j$	$b_{j+1} \dots b_n$
t_3	$a_1 \dots a_i$	$a_{i+1} \dots a_j$	$b_{j+1} \dots b_n$
t_4	$a_1 \dots a_i$	$b_{i+1} \dots b_j$	$a_{j+1} \dots a_n$

Example

- Let R be a relation schema with a set of attributes that are partitioned into 3 nonempty subsets.

Y, Z, W

- We say that $Y \rightarrow\rightarrow Z$ (Y **multidetermines** Z) if and only if for all possible relations $r(R)$

$\langle y_1, z_1, w_1 \rangle \in r$ and $\langle y_1, z_2, w_2 \rangle \in r$

then

$\langle y_1, z_1, w_2 \rangle \in r$ and $\langle y_1, z_2, w_1 \rangle \in r$

- Note that since the behavior of Z and W are identical it follows that

$Y \rightarrow\rightarrow Z$ if $Y \rightarrow\rightarrow W$

Example (Cont.)

- In our example:

$$\begin{aligned} ID \rightarrow\rightarrow & child_name \\ ID \rightarrow\rightarrow & phone_number \end{aligned}$$

- The above formal definition is supposed to formalize the notion that given a particular value of Y (ID) it has associated with it a set of values of Z ($child_name$) and a set of values of W ($phone_number$), and these two sets are in some sense independent of each other.
- Note:
 - If $Y \rightarrow Z$ then $Y \rightarrow\rightarrow Z$
 - Indeed we have (in above notation) $Z_1 = Z_2$
The claim follows.

Theory of MVDs

- From the definition of multivalued dependency, we can derive the following rule:
 - If $\alpha \rightarrow \beta$, then $\alpha \rightarrow\rightarrow \beta$
- That is, every functional dependency is also a multivalued dependency
- The **closure** D^+ of D is the set of all functional and multivalued dependencies logically implied by D .
 - We can compute D^+ from D , using the formal definitions of functional dependencies and multivalued dependencies.
 - We can manage with such reasoning for very simple multivalued dependencies, which seem to be most common in practice
 - For complex dependencies, it is better to reason about sets of dependencies using a system of inference rules (see Appendix C).

Use of Multivalued Dependencies

- We use multivalued dependencies in two ways:
 1. To test relations to **determine** whether they are legal under a given set of functional and multivalued dependencies
 2. To specify **constraints** on the set of legal relations. We shall thus concern ourselves *only* with relations that satisfy a given set of functional and multivalued dependencies.
- If a relation r fails to satisfy a given multivalued dependency, we can construct a relation r' that does satisfy the multivalued dependency by adding tuples to r .

Fourth Normal Form

- A relation schema R is in **4NF** with respect to a set D of functional and multivalued dependencies if for all multivalued dependencies in D^+ of the form $\alpha \twoheadrightarrow \beta$, where $\alpha \subseteq R$ and $\beta \subseteq R$, at least one of the following hold:
 - $\alpha \twoheadrightarrow \beta$ is trivial (i.e., $\beta \subseteq \alpha$ or $\alpha \cup \beta = R$)
 - α is a superkey for schema R
- If a relation is in 4NF it is in BCNF

Further Normal Forms

- **Join dependencies** generalize multivalued dependencies
 - lead to **project-join normal form (PJNF)** (also called **fifth normal form**)
- A class of even more general constraints, leads to a normal form called **domain-key normal form**.
- Problem with these generalized constraints: are hard to reason with, and no set of sound and complete set of inference rules exists.
- Hence rarely used

Final Thoughts on Design Process

Overall Database Design Process

- We have assumed schema R is given
 - R could have been generated when converting an ER diagram to a set of tables.
 - R could have been a single relation containing *all* attributes that are of interest (called **universal relation**).
 - Normalization breaks R into smaller relations.
 - R could have been the result of some ad hoc design of relations, which we then test/convert to normal form.

ER Model and Normalization

- When an ER diagram is carefully designed, identifying all entities correctly, the tables generated from the ER diagram should not need further normalization.
- However, in a real (imperfect) design, there can be functional dependencies from non-key attributes of an entity to other attributes of the entity
 - Example: an *employee* entity with attributes *department_name* and *building*, and a functional dependency $\text{department_name} \rightarrow \text{building}$
 - Good design would have made department an entity
- Functional dependencies from non-key attributes of a relationship set possible, but rare --- most relationships are binary

Denormalization for Performance

- May want to use non-normalized schema for performance
- For example, displaying *prereqs* along with *course_id*, and *title* requires join of *course* with *prereq*
- Alternative 1: Use denormalized relation containing attributes of *course* as well as *prereq* with all above attributes
 - faster lookup
 - extra space and extra execution time for updates
 - extra coding work for programmer and possibility of error in extra code
- Alternative 2: use a materialized view defined as
$$course \bowtie prereq$$
 - Benefits and drawbacks same as above, except no extra coding work for programmer and avoids possible errors

Other Design Issues

- Some aspects of database design are not caught by normalization
- Examples of bad database design, to be avoided:

Instead of *earnings* (*company_id*, *year*, *amount*), use

- *earnings_2004*, *earnings_2005*, *earnings_2006*, etc., all on the schema (*company_id*, *earnings*).
 - Above are in BCNF, but make querying across years difficult and needs new table each year
- *company_year* (*company_id*, *earnings_2004*, *earnings_2005*, *earnings_2006*)
 - Also in BCNF, but also makes querying across years difficult and requires new attribute each year.
 - Is an example of a **crosstab**, where values for one attribute become column names
 - Used in spreadsheets, and in data analysis tools

Recap

- Functional and Multi-valued Dependencies
 - Axioms
 - Closure
 - Minimal Cover
 - Attribute Closure
- Redundancy and lossless decomposition
- Normal-Forms
 - 1NF, 2NF, 3NF
 - BCNF
 - 4NF, 5NF

End of Chapter

Proof of Correctness of 3NF Decomposition Algorithm

Correctness of 3NF Decomposition Algorithm

- 3NF decomposition algorithm is dependency preserving (since there is a relation for every FD in F_c)
- Decomposition is lossless
 - A candidate key (C) is in one of the relations R_i in decomposition
 - Closure of candidate key under F_c must contain all attributes in R .
 - Follow the steps of attribute closure algorithm to show there is only one tuple in the join result for each tuple in R_i

Correctness of 3NF Decomposition Algorithm (Cont'd.)

Claim: if a relation R_i is in the decomposition generated by the above algorithm, then R_i satisfies 3NF.

- Let R_i be generated from the dependency $\alpha \rightarrow \beta$
- Let $\gamma \rightarrow B$ be any non-trivial functional dependency on R_i . (We need only consider FDs whose right-hand side is a single attribute.)
- Now, B can be in either β or α but not in both. Consider each case separately.

Correctness of 3NF Decomposition (Cont'd.)

- Case 1: If B in β :
 - If γ is a superkey, the 2nd condition of 3NF is satisfied
 - Otherwise α must contain some attribute not in γ
 - Since $\gamma \rightarrow B$ is in F^+ it must be derivable from F_c , by using attribute closure on γ .
 - Attribute closure not have used $\alpha \rightarrow \beta$. If it had been used, α must be contained in the attribute closure of γ , which is not possible, since we assumed γ is not a superkey.
 - Now, using $\alpha \rightarrow (\beta - \{B\})$ and $\gamma \rightarrow B$, we can derive $\alpha \rightarrow B$ (since $\gamma \subseteq \alpha \beta$, and $B \notin \gamma$ since $\gamma \rightarrow B$ is non-trivial)
 - Then, B is extraneous in the right-hand side of $\alpha \rightarrow \beta$; which is not possible since $\alpha \rightarrow \beta$ is in F_c .
 - Thus, if B is in β then γ must be a superkey, and the second condition of 3NF must be satisfied.

Correctness of 3NF Decomposition (Cont'd.)

- Case 2: B is in α .
 - Since α is a candidate key, the third alternative in the definition of 3NF is trivially satisfied.
 - In fact, we cannot show that γ is a superkey.
 - This shows exactly why the third alternative is present in the definition of 3NF.

Q.E.D.
